Chapter 8 Rotational Motion Banked Airplanes

An airplane banks as it turns along a horizontal circular path in the air. Except for the thrust of its engines and air resistance, the two significant forces on the plane are gravitational mg (vertical) and lift L (perpendicular to the wings).

Vector Component Analysis:
With a ruler and a pencil, resolve vector L into two perpendicular components, horizontal L_x and vertical L_y . Make these vectors dashed to distinguish them from L .

Circle the correct answers.

1. The velocity of the airplane at any instant is
[along the radius of] [tangent to] its circular path.
2. If L were somehow replaced with L_x and L_y ,
the airplane [would] [would not] behave the
same as being supported by L .
3. Since the airplane doesn't accelerate vertically, component L_y must be
[greater than] [less than] [equal and opposite to] mg .
4. Since the plane continues in circular motion, component L_x must equal [zero] [m^2/r]
and be a [centripetal] [centrifugal] [nonexistent] force. Furthermore, L_x is
[along the radius of] [tangent to] the circular path.

Vector Resultant Analysis:

5. Rather than resolving L into horizontal and
vertical components, use your pencil to
sketch the resultant of mg and L using the
parallelogram rule.
6. The resultant lies in a [horizontal] [vertical]
direction and [toward] [away from] the center
of the circular path. The resultant of mg and L is a
[centripetal] [centrifugal] force.
7. The resultant of mg and L is the same as [L_x] [L_y].

Challenge: Explain in your own words why the resultant of two vectors can be the same as a single component of one of them.
