

GENETIC CHANGES AND CANCER

HOW GENETIC INFORMATION CREATES PROTEINS

RNA

mRNA is also made of four bases: adenine (A), uracil (U), guanine (G), and cytosine (C). mRNA moves from the nucleus to the cytoplasm where it interacts with ribosomes, the protein factories of the cell. There, through a process called **translation**, mRNA is translated into amino acids. A sequence of three mRNA bases is called a **codon**, and each codon is translated into a specific amino acid. There are 20 different kinds of amino acids in humans.

Codons

Growing protein chain

PROTEIN

As an mRNA molecule is translated, a chain of amino acids is formed. The chain eventually folds into a three-dimensional protein. The shape of a protein determines its function. Proteins have millions of functions in cells.

TYPES OF GENETIC MUTATIONS IN CANCER

DNA alterations can affect the structure, function, and amount of the corresponding proteins. All of these effects can change a cell's behavior from normal to cancerous. For example, a genetic alteration can intensify or eliminate the protein's function, which could make cells divide uncontrollably. Many different kinds of genetic mutations are found in cancer cells, including missense, nonsense, and frameshift mutations and chromosome rearrangements.

MISSENSE MUTATION

Original	CTA LEU (leucine)	TGG TRP (tryptophan)	GTA VAL (valine)	DNA Amino Acids
Mutation	CTA LEU (leucine)	TGT CYS (cysteine)	GTA VAL (valine)	DNA Amino Acids

A missense mutation is a change of a single DNA base that results in a change in the amino acid sequence. Sometimes a single amino acid change can greatly alter the protein's function.

NONSENSE MUTATION

Original	CTA LEU (leucine)	TGG TRP (tryptophan)	GTA VAL (valine)	DNA Amino Acids
Mutation	CTA LEU (leucine)	TGA STOP	GTA VAL (valine)	DNA Amino Acids

A nonsense mutation is a change of a single DNA base that creates a "stop" codon, which terminates translation. The result is a shortened protein that may not function or that may have an abnormal function.

FRAMESHIFT MUTATION

Original	CTA LEU (leucine)	TGG TRP (tryptophan)	GTA VAL (valine)	DNA Amino Acids
Mutation	CTA LEU (leucine)	ATG MET (methionine)	GGT GLY (glycine)	DNA Amino Acids

A frameshift mutation results from the addition or removal of DNA bases that shifts the DNA sequence and the corresponding amino acid sequence. The result is a protein whose sequence, structure, and function are very different from those of the original protein.

CHROMOSOME REARRANGEMENTS

DNA is wound tightly into structures called chromosomes. Chromosome rearrangements can occur when a piece of a chromosome breaks and is lost entirely (deletion), moves to a different chromosomal location (translocation), flips directions (inversion), or is repeated (duplication). These rearrangements can alter several genes at once. For example, they can generate fusion genes, in which parts of two separate genes are joined together. Proteins made from fusion genes sometimes cause cancer.

The Genetics of Cancer B.A. Ponder, M.J. Waring, 2012-12-06 It has been recognized for almost 200 years that certain families seem to inherit cancer It is only in the past decade however that molecular genetics and epidemiology have combined to define the role of inheritance in cancer more clearly and to identify some of the genes involved The causative genes can be tracked through cancer prone families via genetic linkage and positional cloning Several of the genes discovered have subsequently been proved to play critical roles in normal growth and development There are also implications for the families themselves in terms of genetic testing with its attendant dilemmas if it is not clear that useful action will result The chapters in The Genetics of Cancer illustrate what has already been achieved and take a critical look at the future directions of this research and its potential clinical applications

Mitochondrial Genetics and Cancer Gabriel D. Dakubo,2010-03-23 With very few exceptions eukaryotic cells possess two interdependent genomes chromosomal and extra chromosomal Over the past several decades cancer search has focused primarily on deciphering the intricate alterations in the chromosomal genome with until recently very little attention to its cytoplasmic counterpart In spite of the enormous complexity of the nuclear genome which we now fully appreciate after completion of the human genome project the efforts of cancer researchers are commendable in terms of the tremendous gains made in unraveling the numerous genetic changes in cancer These changes include deletions of tumor suppressor genes oncogenes and caretaker genes that are often mutated in cancer Recent studies of genomic profiles are uncovering even more altered and mutated genes in cancer Besides these findings several therapeutic targets for chemotherapy are currently made from studies of altered nuclear genetic pathways In spite of all these positive efforts the war on cancer declared in 1971 by Richard Nixon is far from being won Indeed the failure of chemotherapy is obvious to clinicians oncologists and their patients alike Moreover the global incidence and prevalence of cancer continue to rise What are we missing Which direction should we be taking Of course modern integrated nuclear genomics proteomics and metabolomics should provide important clues to carcinogenesis but the contribution of cytoplasmic genetic alterations to carcinogenesis cannot be neglected
